< ロ > < 同 > < 三 > .

- Rissanen (1983) introduced the notion of *stochastic chains with variable length memory* as a universal system for data compression
- He called this model a *finitely generated source* or a *tree machine*.
- Recently this model has become popular in the Statistics literature under the name of *variable length Markov chain* coined by Bühlman and Wyner (1999).
- in Bio-informatics it was also called a *probabilistic suffix tree* (Bejerano and Yona 2001).

A VLMC is a stationary stochastic chain  $(X_n)$  taking values on a finite alphabet A and characterized by two elements:

• The set of all contexts.

A context  $X_{n-\ell}, \ldots, X_{n-1}$  is the finite portion of the past  $X_{-\infty}, \ldots, X_{n-1}$  which is relevant to predict the next symbol  $X_n$ .

• A family of transition probabilities associated to each context.

Given a context, its associated transition probability gives the distribution of occurrence of the next symbol immediately after the context.

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ののの

A stationary stochastic chain  $(X_n)$  is *consistent* with a probabilistic context tree  $(\tau, p)$  if for any infinite past  $x_{-\infty}^{-1}$  and any symbol  $a \in \mathcal{A}$  we have

$$\mathbb{P}\left\{X_{0} = a \mid X_{-\infty}^{-1} = x_{-\infty}^{-1}\right\} = p(a \mid x_{-\ell}^{-1}),$$

where  $x_{-\ell}^{-1}$  is the only element of  $\tau$  which is a suffix of the sequence  $x_{-\infty}^{-1}$ .

## • The suffix $x_{-\ell}^{-1}$ is called the *context* of the sequence $x_{-\infty}^{-1}$

- The length of the context ℓ = ℓ(x<sup>-1</sup><sub>-∞</sub>) is a function of the sequence.
- The suffix property implies that the set {*l*(X<sup>-1</sup><sub>-∞</sub>) = *k*} is measurable with respect to the *σ*-algebra generated by X<sup>-1</sup><sub>-k</sub>.

・ロト ・ 同ト ・ ヨト ・ ヨト ・ ヨ

# Why variable length memory chains are interesting?

#### They constitute an interesting class of chains of infinite order;

- They are able to model candidates to model rhythmic contours in natural languages, or families of proteins!
- This is due to the fact that the tree of contexts *τ* describes structural dependencies present in the data.
- More precisely, Rissanen's algorithm *Context* captures structural dependencies of the data.

# The algorithm Context

- Starting with a finite sample  $X_1, \ldots, X_n$
- First construct a candidate context  $X_{n-k(n)}^{n-1}$  where  $k(n) = C \log n$
- Then decide to shorten or not this candidate context using some *gain function*. For instance the log-likelihood ratio statistics.
- The intuitive reason behind the choice of the upper bound length *C* log *n* is the impossibility of estimating the probability of sequences of length longer than log *n* based on a sample of length *n*.

## Estimation of the probability transitions

• For any finite string  $w_{-j}^{-1}$  with  $j \le n$ , denote  $N_n(w_{-j}^{-1})$  the number of occurrences of the string in the sample

$$N_n(w_{-j}^{-1}) = \sum_{t=0}^{n-j} \mathbf{1} \left\{ X_t^{t+j-1} = w_{-j}^{-1} \right\}$$

If ∑<sub>b∈A</sub> N<sub>n</sub>(w<sup>-1</sup><sub>-k</sub>b) > 0, we define the estimator of the transition probability p by

$$\hat{p}_n(a|w_{-k}^{-1}) = rac{N_n(w_{-k}^{-1}a)}{\sum_{b\in\mathcal{A}}N_n(w_{-k}^{-1}b)}.$$

イロト イポト イヨト イヨト 三油

**Theorem.** Given a realization  $X_0, \ldots, X_{n-1}$  of a probabilistic suffix tree  $(\tau, p)$  with **finite height**, then

$$\mathbb{P}\left\{\hat{\ell}(X_0^{n-1}) \neq \ell(X_0^{n-1})\right\} \longrightarrow 0$$

as  $n \to \infty$ .

In the unbounded case, the compactness of  $\mathcal{A}^{\mathbb{Z}}$  assures that there is at least one stationary stochastic chain consistent with a continuous probabilistic suffix tree. Uniqueness requires further conditions.

# Type A probabilistic context trees

A **type A** probabilistic context tree  $(\tau, p)$  on  $\mathcal{A}$  satisfies the conditions:

• Weakly non-nullness, that is

$$\sum_{a\in\mathcal{A}}\inf_{w\in\tau}p(a\mid w)>0;$$

• Continuity

 $\beta(k) := \max_{a \in \mathcal{A}} \sup\{|p(a \mid w) - p(a \mid v)|, v \in \tau, w \in \tau \text{ with } w_{-k}^{-1} = v_{-k}^{-1}$ 

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ののの

as  $k \to \infty$ .

•  $\{\beta(k)\}_k \in \mathbb{N}$  is called the **continuity rate**.

# The chi-square approximation

- At each step of the algoithm Context we perform at most k(n) sequential tests, where  $k(n) \rightarrow \infty$  as *n* diverges.
- To control the error in the chi-square approximation we use a well-known asymptotic expansion for the distribution of Λ<sub>n</sub>(*i*, *w*) due to Hayakawa (1970) which implies that

$$\mathbb{P}\left\{\Lambda_n(i,w)\leq x\mid H_0^i\right\}=\mathbb{P}\left\{\chi^2\leq x\right\}+D/n\,,$$

where *D* is a positive constant and  $\chi^2$  is random variable with distribution chi-square with |A| - 1 degrees of freedom.

# Another version of the algorithm Context

 In a recent paper with Véronique Maume and Bernard Schmitt we propose to use as *gain* function

$$\Delta_n(j) = \max_{a \in A} |\hat{p}_n(a|X_{n-j}^{n-1}) - \hat{p}_n(a|X_{n-(j-1)}^{n-1})|$$

where 
$$1 \le j \le k(n)$$
;  
and define  $\hat{\ell}(X_0^{n-1})$  as

$$\max\{j=1,\ldots,k(n):\Delta_n(j)<\delta\},\$$

where  $\delta > 0$  is any fixed threshold.

 If the contexts are bounded, then any δ > 0 would do the job.

# Another version of the algorithm Context

 In a recent paper with Véronique Maume and Bernard Schmitt we propose to use as *gain* function

$$\Delta_n(j) = \max_{a \in A} |\hat{p}_n(a|X_{n-j}^{n-1}) - \hat{p}_n(a|X_{n-(j-1)}^{n-1})|,$$

where 
$$1 \le j \le k(n)$$
;  
and define  $\hat{\ell}(X_0^{n-1})$  as

٥

$$\max\{j=1,\ldots,k(n):\Delta_n(j)<\delta\},\$$

where  $\delta > 0$  is any fixed threshold.

• If the contexts are bounded, then any  $\delta > 0$  would do the job.
