Riemannian metrics

1.1 Introduction

A Riemannian metric is a family of smoothly varying inner products on the tangent spaces of a smooth manifold. Riemannian metrics are thus infinitesimal objects, but they can be used to measure distances on the manifold. They were introduced by Riemann in his seminal work \([\text{Rie53}]\) in 1854. At that time, the concept of a manifold was extremely vague and, except for some known global examples, most of the work of the geometers focused on local considerations, so the modern concept of a Riemannian manifold took quite some time to evolve to its present form. We point out the seemingly obvious fact that a given smooth manifold can be equipped with many different Riemannian metrics. This is really one of the great insights of Riemann, namely, the separation between the concepts of space and metric.

1.2 Riemannian metrics

Let \( M \) be a smooth manifold. A \textit{Riemannian metric} \( g \) on \( M \) is a smooth family of inner products on the tangent spaces of \( M \). Namely, \( g \) associates to each \( p \in M \) a positive definite symmetric bilinear form on \( T_pM \),

\[
g_p : T_pM \times T_pM \to \mathbb{R},
\]

and the smoothness condition on \( g \) refers to the fact that the function

\[
p \in M \to g_p(X_p, Y_p) \in \mathbb{R}
\]

must be smooth for every locally defined smooth vector fields \( X, Y \) in \( M \). A \textit{Riemannian manifold} is a pair \( (M, g) \) where \( M \) is a differentiable manifold and \( g \) is a Riemannian metric on \( M \). Later on (but not in this chapter), we will often simplify the notation and refer to \( M \) as a Riemannian manifold where the Riemannian metric is implicit.

Let \( (M, g) \) be a Riemannian manifold. If \( (U, \varphi = (x^1, \ldots, x^n)) \) is a chart of \( M \), a local expression for \( g \) can be given as follows. Let \( \{\frac{\partial}{\partial x^1}, \ldots, \frac{\partial}{\partial x^n}\} \) be the coordinate vector fields, and let \( \{dx^1, \ldots, dx^n\} \) be the dual 1-forms. For \( p \in U \) and \( u, v \in T_pM \), we write

\[
u = \sum_j v^j \frac{\partial}{\partial x^j} \bigg|_p.
\]

© Claudio Gorodski 2012
Then, by bilinearity,

\[ g_p(u, v) = \sum_{i,j} u^i v^j g_p \left( \frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j} \right) = \sum_{i,j} g_{ij}(p)u^i v^j, \]

where we have set \( g_{ij}(p) = g_p \left( \frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j} \right). \)

Note that \( g_{ij} = g_{ji}. \) Hence we can write

\[ (1.2.1) \quad g = \sum_{i,j} g_{ij} dx^i \otimes dx^j = \sum_{i \leq j} \tilde{g}_{ij} dx^i dx^j, \]

where \( \tilde{g}_{ii} = g_{ii}, \) and \( \tilde{g}_{ij} = 2g_{ij} \) if \( i < j. \)

Next, let \((U', \varphi' = (x^1', \ldots, x^n'))\) be another chart of \( M \) such that \( U \cap U' \neq \emptyset. \) Then

\[ \frac{\partial}{\partial x'^i} = \sum_k \frac{\partial x^k}{\partial x^i'} \frac{\partial}{\partial x^k}, \]

so the relation between the local expressions of \( g \) with respect to \((U, \varphi)\) and \((U', \varphi')\) is given by

\[ g_{ij}' = g \left( \frac{\partial}{\partial x'^i}, \frac{\partial}{\partial x'^j} \right) = \sum_{k,l} \frac{\partial x^k}{\partial x'^i} \frac{\partial x^l}{\partial x'^j} g_{kl}. \]

1.2.2 Example The canonical Euclidean metric is expressed in Cartesian coordinates by \( g = dx^2 + dy^2. \) Changing to polar coordinates \( x = r \cos \theta, \; y = r \sin \theta \) yields that

\[ dx = \cos \theta dr - r \sin \theta d\theta \quad \text{and} \quad dy = \sin \theta dr + r \cos \theta d\theta, \]

so

\[ g = dx^2 + dy^2 = (\cos^2 \theta dr^2 + r^2 \sin^2 \theta d\theta^2 - 2r \sin \theta \cos \theta dr d\theta) + (\sin^2 \theta dr^2 + r^2 \cos^2 \theta d\theta^2 + 2r \sin \theta \cos \theta dr d\theta) = dr^2 + r^2 d\theta^2. \]

The functions \( g_{ij} \) are smooth on \( U \) and, for each \( p \in U, \) the matrix \((g_{ij}(p))\) is symmetric and positive-definite. Conversely, a Riemannian metric in \( U \) can be obviously specified by these data.

1.2.3 Proposition Every smooth manifold can be endowed with a Riemannian metric.

Proof. Let \( M = \bigcup_{\alpha} U_\alpha \) be a covering of \( M \) by domains of charts \( \{(U_\alpha, \varphi_\alpha)\}. \) For each \( \alpha, \) consider the Riemannian metric \( g_\alpha \) in \( U_\alpha \) whose local expression \( ((g_\alpha)_{ij}) \) is the identity matrix. Let \( \{\rho_\alpha\} \) be a smooth partition of unity of \( M \) subordinate to the covering \( \{U_\alpha\}, \) and define

\[ g = \sum_\alpha \rho_\alpha g_\alpha. \]
Since the family of supports of the $\rho_\alpha$ is locally finite, the above sum is locally finite, and hence $g$ is well defined and smooth, and it is bilinear and symmetric at each point. Since $\rho_\alpha \geq 0$ for all $\alpha$ and $\sum_\alpha \rho_\alpha = 1$, it also follows that $g$ is positive definite, and thus is a Riemannian metric in $M$. □

The proof of the preceding proposition suggests the fact that there exists a vast array of Riemannian metrics on a given smooth manifold. Even taking into account equivalence classes of Riemannian manifolds, the fact is that there many uninteresting examples of Riemannian manifolds, so an important part of the work of the differential geometer is to sort out relevant families of examples.

Let $(M, g)$ and $(M', g')$ be Riemannian manifolds. A isometry between $(M, g)$ and $(M', g')$ is a diffeomorphism $f : M \to M'$ whose differential is a linear isometry between the corresponding tangent spaces, namely,

$$g_p(u, v) = g'_{f(p)}(df_p(u), df_p(v)),$$

for every $p \in M$ and $u, v \in T_p M$. We say that $(M, g)$ and $(M', g')$ are isometric Riemannian manifolds if there exists an isometry between them. This completes the definition of the category of Riemannian manifolds and isometric maps. Note that the set of all isometries of a Riemannian manifold $(M, g)$ forms a group, called the isometry group of $(M, g)$, with respect to the operation of composition of mappings, which we will denote by Isom$(M, g)$. Here we quote without proof the following important theorem [MS39].

1.2.4 Theorem (Myers-Steenrod) The isometry group of a Riemannian manifold has the structure of a Lie group with respect to the compact-open topology. Its isotropy subgroup at an arbitrary fixed point is compact.

A local isometry from $(M, g)$ into $(M', g')$ is a smooth map $f : M \to M'$ satisfying the condition that every point $p \in M$ admits a neighborhood $U$ such that the restriction of $f$ to $U$ is an isometry onto its image. In particular, $f$ is a local diffeomorphism.

1.3 Examples

The Euclidean space

The Euclidean space is $\mathbb{R}^n$ equipped with its standard scalar product. The essential feature of $\mathbb{R}^n$ as a smooth manifold is that, since it is the model space for finite dimensional smooth manifolds, it admits a global chart given by the identity map. Of course, the identity map establishes canonical isomorphisms of the tangent spaces of $\mathbb{R}^n$ at each of its points with $\mathbb{R}^n$ itself. Therefore an arbitrary Riemannian metric in $\mathbb{R}^n$ can be viewed as a smooth family of inner products in $\mathbb{R}^n$. In particular, by taking the constant family given by the standard scalar product, we get the canonical Riemannian structure in $\mathbb{R}^n$. In this book, unless explicitly stated, we will always use its canonical metric when referring to $\mathbb{R}^n$ as a Riemannian manifold.

If $(x_1, \ldots, x_n)$ denote the standard coordinates on $\mathbb{R}^n$, then it is readily seen the local expression of the canonical metric is

$$dx_1^2 + \cdots + dx_n^2. \tag{1.3.1}$$

More generally, if a Riemannian manifold $(M, g)$ admits local coordinates such that the local expression of $g$ is as in (1.3.1), then $(M, g)$ is called flat and $g$ is called a flat metric on $M$. Note that, if $g$ is a flat metric on $M$, then the coordinates used to express $g$ as in (1.3.1) immediately define a local isometry between $(M, g)$ and Euclidean space $\mathbb{R}^n$. 

3
Riemannian submanifolds and isometric immersions

Let \((M, g)\) be a Riemannian manifold and consider a immersed submanifold \(\iota : N \to M\). This means that \(N\) is a smooth manifold and \(\iota\) is an injective immersion. Then the Riemannian metric \(g\) induces a Riemannian metric \(g_N\) in \(N\) as follows. Let \(p \in N\). The tangent space \(T_pN\) can be viewed as a subspace of \(T_pM\) via the injective map \(d\iota_p : T_pN \to T_{\iota(p)}M\). We define \((g_N)_p\) to be simply the restriction of \(g\) to this subspace, namely,

\[
(g_N)_p(u, v) = g_{\iota(p)}(d\iota_p(u), d\iota_p(v)),
\]

where \(u, v \in T_pN\). It is clear that \(g_N\) is a Riemannian metric. We call \(g_N\) the induced Riemannian metric in \(N\), and we call \((N, g_N)\) a Riemannian submanifold of \((M, g)\).

Note that the definition of \(g_N\) makes sense even if \(\iota\) is an immersion that is not necessarily injective. In this case, we call \(g_N\) the pulled-back metric, write \(g_N = \iota^*g\), and say that \(\iota : (N, g_N) \to (M, g)\) is an isometric immersion (of course, any immersion must be locally injective).

A very important particular case is that of Riemannian submanifolds of Euclidean space. Historically speaking, the study of Riemannian manifolds was preceded by the theory of curves and surfaces in \(\mathbb{R}^n\). In the classical theory, one uses parametrizations instead of local charts, and these objects are called parametrized curves and parametrized surfaces since they usually already come with the parametrization. In the most general case, the parametrization is only assumed to be smooth. One talks about a regular curve or a regular surface if one wants the parametrization to be an immersion. Of course, in this case it follows that the parametrization is locally an embedding. This is good enough for the classical theory, since it is really concerned with local computations.

The sphere \(S^n\)

The canonical Riemannian metric in the sphere \(S^n\) is the Riemannian metric induced by its embedding in \(\mathbb{R}^n\) as the sphere of unit radius. When one refers to \(S^n\) as a Riemannian manifold with its canonical Riemannian metric, sometimes one speaks of “the unit sphere”, or “the metric sphere”, or the “Euclidean sphere”, or “the round sphere”. One also uses the notation \(S^n(R)\) to specify a sphere of radius \(R\) embedded in \(\mathbb{R}^N\) with the induced metric. In this book, unless explicitly stated, we will always use the canonical metric when referring to \(S^n\) as a Riemannian manifold.

Product Riemannian manifolds

Let \((M_i, g_i)\), where \(i = 1, 2\), denote two Riemannian manifolds. Then the product smooth manifold \(M = M_1 \times M_2\) admits a canonical Riemannian metric \(g\), called the product Riemannian metric, given as follows. The tangent space of \(M\) at a point \(p = (p_1, p_2) \in M_1 \times M_2\) splits as \(T_pM = T_{p_1}M_1 \oplus T_{p_2}M_2\). Given \(u, v \in T_pM\), write accordingly \(u = u_1 + u_2\) and \(v = v_1 + v_2\), and define

\[
g_p(u, v) = g_{p_1}(u_1, v_1) + g_{p_2}(u_2, v_2).
\]

It is clear that \(g\) is a Riemannian metric. Note that it follows from this definition that \(T_{p_1}M_1 \oplus \{0\}\) is orthogonal to \(\{0\} \oplus T_{p_2}M_2\). We will sometimes write that \((M, g) = (M_1, g_1) \times (M_2, g_2)\), or that \(g = g_1 + g_2\).

It is immediate to see that Euclidean space \(\mathbb{R}^n\) is the Riemannian product of \(n\) copies of \(\mathbb{R}\).

Conformal Riemannian metrics

Let \((M, g)\) be a Riemannian manifold. If \(f\) is a nowhere zero smooth function on \(M\), then \(f^2g\) defined by

\[
(f^2g)_p(u, v) = f^2(p)g_p(u, v),
\]

is a Riemannian metric on \(M\). It is called the conformal Riemannian metric on \(M\) with coefficient \(f\).
where $p \in M$, $u, v \in T_p M$, is a new Riemannian metric on $M$ which is said to be \textit{conformal} to $g$. We also say that $(M, g)$ is \textit{conformally flat} if $M$ can be covered by open sets on each of which $g$ is conformal to a flat metric.

\textbf{The real hyperbolic space $RH^n$}

To begin with, consider the Lorentzian inner product in $\mathbb{R}^{n+1}$ given by

$$\langle x, y \rangle = -x_0 y_0 + x_1 y_1 + \cdots + x_n y_n,$$

where $x = (x_0, \ldots, x_n)$, $y = (y_0, \ldots, y_n) \in \mathbb{R}^{n+1}$. We will write $\mathbb{R}^{1,n}$ to denote $\mathbb{R}^{n+1}$ with such a Lorentzian inner product. Note that if $p \in \mathbb{R}^{1,n}$ is such that $\langle p, p \rangle < 0$, then the restriction of $\langle \cdot, \cdot \rangle$ to the orthogonal complement $(\langle p \rangle)^\perp$ is positive-definite. Note also that the equation $\langle x, x \rangle = -1$ defines a two-sheeted hyperboloid in $\mathbb{R}^{1,n}$.

Now we can define the \textit{real hyperbolic space} as the following submanifold of $\mathbb{R}^{1,n}$,

$$RH^n = \{ x \in \mathbb{R}^{1,n} \mid \langle x, x \rangle = -1 \text{ and } x_0 > 0 \},$$

equipped with a Riemannian metric $g$ given by the restriction of $\langle \cdot, \cdot \rangle$ to the tangent spaces at its points. Since the tangent space of the hyperboloid at a point $p$ is given by $(\langle p \rangle)^\perp$, the Riemannian metric $g$ turns out to be well defined. Actually, this submanifold is sometimes called the \textit{hyperboloid model of $RH^n$} (compare exercises 3 and 4). Of course, as a smooth manifold, $RH^n$ is diffeomorphic to $\mathbb{R}^n$.

\textbf{Riemannian coverings}

A \textit{Riemannian covering} between two Riemannian manifolds is a smooth covering that is also a local isometry.

Recall that an action of a discrete group $\Gamma$ on a topological space is called: \textit{free} if no non-trivial element of $\Gamma$ has fixed points; \textit{properly discontinuous} if any two points of the space have neighborhoods $U$ and $V$ such that $\{ \gamma \in \Gamma \mid \gamma U \cap V \neq \emptyset \}$ is a finite set.

If $\tilde{M}$ is a smooth manifold and $\Gamma$ is a discrete group acting freely and properly discontinuously by diffeomorphisms on $\tilde{M}$, then the quotient space $M = \tilde{M}/\Gamma$ endowed with the quotient topology admits a unique structure of smooth manifold such that the projection $\pi : \tilde{M} \to M$ is a smooth regular covering. If we assume, in addition, that $M$ is equipped with a Riemannian metric $\tilde{g}$ and $\Gamma$ acts on $\tilde{M}$ by isometries, then we can show that there is a unique Riemannian metric $g$ on $M$, called the \textit{quotient metric}, so that $\pi : (\tilde{M}, \tilde{g}) \to (M, g)$ becomes a Riemannian covering, as follows. Given a point $p \in M$ and tangent vectors $u, v \in T_p M$, we set

\begin{equation}
\tag{1.3.2}
g_p(u, v) = \tilde{g}_p((d\pi_\tilde{p})^{-1}(u), (d\pi_\tilde{p})^{-1}(v)),
\end{equation}

where $\tilde{p}$ is any point in the fiber $\pi^{-1}(p)$. We claim that this definition does not depend on the choice of point in $\pi^{-1}(p)$. In fact, if $\tilde{p}'$ is another point in $\pi^{-1}(p)$, there is a unique $\gamma \in \Gamma$ such that $\gamma(\tilde{p}) = \tilde{p}'$. Since $\pi \circ \gamma = \pi$, the chain rule gives that $d\pi_{\gamma(p)} \circ d\gamma_{\tilde{p}} = d\pi_{\tilde{p}}$, so

$$\tilde{g}_{\tilde{p}}((d\pi_{\tilde{p}})^{-1}(u), (d\pi_{\tilde{p}})^{-1}(v)) = \tilde{g}_{\tilde{p}}((d\gamma_{\tilde{p}})^{-1}(d\pi_{\gamma(p)})^{-1}(u), (d\gamma_{\tilde{p}})^{-1}(d\pi_{\gamma(p)})^{-1}(v)) = \tilde{g}_{\tilde{p}'}((d\pi_{\tilde{p}'})^{-1}(u), (d\pi_{\tilde{p}'})^{-1}(v)),
$$

since $d\gamma_{\tilde{p}} : T_{\tilde{p}} \tilde{M} \to T_{\tilde{p}'} \tilde{M}$ is a linear isometry, checking the claim. Next, we show that $g$ is smooth. In fact, selecting open sets $U$ in $M$ and $\tilde{U}$ in $\tilde{M}$ such that $\pi|_{\tilde{U}} : \tilde{U} \to U$ is a diffeomorphism, we can rewrite (1.3.2) as

$$g_q(u, v) = \tilde{g}_{\pi|_{\tilde{U}}}^{-1}(q)(d(\pi|_{\tilde{U}})^{-1}(u), (d(\pi|_{\tilde{U}})^{-1}(v)),
$$

5
where $q \in U$, which shows that $g$ is smooth in $U$. Since we can cover $M$ by such sets $U$, it follows that $g$ is smooth. Finally, the requirement that $\pi$ be a local isometry forces $g$ to be given by formula (1.3.2), and this shows the uniqueness of $g$.

On the other hand, if we start with a Riemannian manifold $(M, g)$ and a smooth covering $\pi : \tilde{M} \to M$, then $\pi$ is in particular an immersion, so we can endow $\tilde{M}$ with the pulled-back metric $\tilde{g}$ and $\pi : (\tilde{M}, \tilde{g}) \to (M, g)$ becomes a Riemannian covering. Let $\Gamma$ denote the group of deck transformations of $\pi : \tilde{M} \to M$. An element $\gamma \in \Gamma$ satisfies $\pi \circ \gamma = \pi$. Since $\pi$ is a local isometry, we have that $\gamma$ is a local isometry, and being a bijection, it must be a global isometry. Hence the group $\Gamma$ consists of isometries of $\tilde{M}$. If we assume, in addition, that $\tilde{\pi} : \tilde{M} \to M$ is a regular covering (for instance, this is true if $\pi : \tilde{M} \to M$ is the universal covering), then $M$ is diffeomorphic to the orbit space $\tilde{M}/\Gamma$, and since we already know that $\pi : (\tilde{M}, \tilde{g}) \to (M, g)$ is a Riemannian covering, it follows from the uniqueness result of the previous paragraph that $g$ must be the quotient metric of $\tilde{g}$.

**The real projective space $\mathbb{R}P^n$**

As a set, $\mathbb{R}P^n$ is the set of all lines through the origin in $\mathbb{R}^{n+1}$. It can also be naturally viewed as a quotient space in two ways. In the first one, we define an equivalence relation among points in $\mathbb{R}^{n+1} \setminus \{0\}$ by declaring $x$ and $y$ to be equivalent if they lie in the same line, namely, if there exists $\lambda \in \mathbb{R} \setminus \{0\}$ such that $y = \lambda x$. In the second one, we simply note that every line meets the unit sphere in $\mathbb{R}^{n+1}$ in two antipodal points, so we can also view $\mathbb{R}P^n$ as a quotient space of $S^n$ and, in this case, $x, y \in S^n$ are equivalent if and only if $y = \pm x$. Of course, in both cases $\mathbb{R}P^n$ acquires the same quotient topology.

Next, we reformulate our point of view slightly by introducing the group $\Gamma$ consisting of two isometries of $S^n$, namely the identity map and the antipodal map. Then $\Gamma$ obviously acts freely and properly discontinuously on $S^n$, and the resulting quotient smooth manifold is plainly $\mathbb{R}P^n$. Furthermore, as the action of $\Gamma$ is also isometric, $\mathbb{R}P^n$ immediately acquires a quotient Riemannian metric.

**Flat tori**

A lattice $\Gamma$ in $\mathbb{R}^n$ (or, more generally, in a real vector space) is the subset of $\mathbb{R}^n$ consisting of integral linear combinations of the vectors in a fixed basis. Namely, if $\{v_1, \ldots, v_n\}$ is a basis of $\mathbb{R}^n$, then it defines a lattice $\Gamma$ comprising all vectors of the form $\sum_{j=1}^n m_j v_j$, where $m_j \in \mathbb{Z}$. The elements of $\Gamma$ can be identified with the translations of $\mathbb{R}^n$ that they define and, in this way, $\Gamma$ becomes a discrete group acting freely, properly discontinuously and isometrically on $\mathbb{R}^n$ (of course, another point of view is to regard $\Gamma$ as a discrete subgroup of the additive group of $\mathbb{R}^n$). The quotient Riemannian manifold $\mathbb{R}^n/\Gamma$ is called a flat torus. Note that $\mathbb{R}^n/\Gamma$ is compact since it coincides with the image of the projection of $\{ \sum_{j=1}^n x_j v_j | 0 \leq x_j \leq 1 \}$.

As a smooth manifold, $\mathbb{R}^n/\Gamma$ is diffeomorphic to the product of $n$ copies of $S^1$, which we denote by $T^n$. In fact, define a map $f : \mathbb{R}^n \to T^n$ by setting

$$f \left( \sum_{j=1}^n x_j v_j \right) = (e^{2\pi i x_1}, \ldots, e^{2\pi i x_n}),$$

where we view $S^1$ as the set of unit complex numbers. Then $f$ is constant on $\Gamma$, so it induces a smooth bijection $\bar{f} : \mathbb{R}^n/\Gamma \to T^n$. Denote the Riemannian covering $\mathbb{R}^n \to \mathbb{R}^n/\Gamma$ by $\pi$. Then $f = \bar{f} \circ \pi$ composed on the left with an appropriate chart of $T^n$ is simply the identity. It follows that $\bar{f}$ is a diffeomorphism.
Let \( M = \mathbb{R}^2 \), let \( \{v_1, v_2\} \) be a basis of \( \mathbb{R}^2 \), and let \( \Gamma \) be the discrete group of transformations of \( \mathbb{R}^2 \) generated by

\[
\gamma_1(x_1v_1 + x_2v_2) = \left( x_1 + \frac{1}{2} \right) v_1 - x_2 v_2 \quad \text{and} \quad \gamma_2(x_1v_1 + x_2v_2) = x_1v_1 + (x_2 + 1)v_2.
\]

It is easy to see that \( \Gamma \) acts freely and properly discontinuously on \( \mathbb{R}^2 \), so we get a quotient manifold \( \mathbb{R}^2/\Gamma \) which is called the Klein bottle \( K^2 \). It is a compact non-orientable manifold, since \( \gamma_2 \) reverses the orientation of \( \mathbb{R}^2 \). It follows that \( K^2 \) cannot be embedded in \( \mathbb{R}^3 \) by the Jordan-Brouwer separation theorem; however, it is easy to see that it can immersed there.

Consider \( \mathbb{R}^2 \) equipped with its canonical metric. Note that \( \gamma_1 \) is always an isometry of \( \mathbb{R}^2 \), but so is \( \gamma_2 \) if and only if the basis \( \{v_1, v_2\} \) is orthogonal. In this case, \( \Gamma \) acts by isometries on \( \mathbb{R}^2 \) and \( K^2 \) inherits a flat metric so that the projection \( \mathbb{R}^2 \to K^2 \) is a Riemannian covering.

**Riemannian submersions**

Let \( \pi : M \to N \) be a smooth submersion between two smooth manifolds. Then \( \mathcal{V}_p = \ker d\pi_p \) for \( p \in M \) defines a smooth distribution on \( M \) which is called the vertical distribution. Clearly, \( \mathcal{V} \) can also be given by the tangent spaces of the fibers of \( \pi \).

In general, there is no canonical choice of a complementary distribution of \( \mathcal{V} \) in \( TM \), but in the case in which \( M \) comes equipped with a Riemannian metric, one can naturally construct such a complement \( \mathcal{H} \) by setting \( \mathcal{H}_p \) to be the orthogonal complement of \( \mathcal{V}_p \) in \( T_pM \). Then \( \mathcal{H} \) is a smooth distribution which is called the horizontal distribution. Note that \( d\pi_p \) induces an isomorphism between \( \mathcal{H}_p \) and \( T_{\pi(p)}N \) for every \( p \in M \).

Having this preliminary remarks at hand, we can now define a smooth submersion \( \pi : (M, g) \to (N, h) \) between two Riemannian manifolds to be a Riemannian submersion if \( d\pi_p \) induces an isometry between \( \mathcal{H}_p \) and \( T_{\pi(p)}N \) for every \( p \in M \). Note that Riemannian coverings are particular cases of Riemannian submersions.

Let \( (M, g) \) and \( (N, h) \) be Riemannian manifolds. A quite trivial example of a Riemannian submersion is the projection \( (M \times N, g + h) \to (M, g) \) (or \( (M \times N, g + h) \to (N, h) \)). More generally, if \( f \) is a nowhere zero smooth function on \( N \), the projection from \( (M \times N, f^2g + h) \) onto \( (N, h) \) is a Riemannian submersion. In this case, the fibers of the submersion are not isometric one to the other. A Riemannian manifold of the form \( (M \times N, f^2g + h) \) is called a warped product.
The complex projective space \( \mathbb{C}P^n \)

The definition of \( \mathbb{C}P^n \) is similar to that of \( \mathbb{R}P^n \) in that we replace real numbers by complex numbers. Namely, as a set, \( \mathbb{C}P^n \) is the set of all complex lines through the origin in \( \mathbb{C}^{n+1} \), so it can be viewed as the quotient of \( \mathbb{C}^{n+1} \setminus \{0\} \) by the multiplicative group \( \mathbb{C} \setminus \{0\} \) as well as the quotient of the unit sphere \( S^{2n+1} \) of \( \mathbb{C}^{n+1} \) (via its canonical identification with \( \mathbb{R}^{2n+2} \)) by the multiplicative group of unit complex numbers \( S^1 \). Here the action of \( S^1 \) on \( S^{2n+1} \) is given by multiplication of the coordinates (since \( S^1 \) is commutative, it is unimportant whether \( S^1 \) multiplies on the left or on the right).

Now \( \mathbb{C}P^n \) is equipped with a quotient topology. First, we note that the projection \( S^{2n+1} \to \mathbb{C}P^n \) is an open map. Since the orbits of \( S^1 \) in \( S^{2n+1} \) are compact, now it is not difficult to see that the quotient topology is Hausdorff. Moreover, the projection of a countable basis of \( S^{2n+1} \) yields a countable basis of \( \mathbb{C}P^n \). Next, there is a convenient way of describing the manifold structure of \( \mathbb{C}P^n \). For each \( p \in \mathbb{C}P^n \), we construct a local chart around \( p \). We will use the standard Hermitian inner product of \( \mathbb{C}^{n+1} \), which we denote by \( (\cdot,\cdot) \). View \( p \) as a one-dimensional subspace of \( \mathbb{C}^{n+1} \) and denote its Hermitian orthogonal complement by \( p^\perp \). The subset of all lines which are not parallel to \( p^\perp \) is an open subset of \( \mathbb{C}P^n \), which we denote by \( \mathbb{C}P^n \setminus p^\perp \). Fix a unit vector \( \tilde{p} \) lying in the line \( p \). The local chart is

\[
\varphi^p : \mathbb{C}P^n \setminus p^\perp \to p^\perp', \quad q \mapsto \frac{1}{(q,\tilde{p})} q - \tilde{p},
\]

where \( \tilde{q} \) is any nonzero vector lying in \( q \). In other words, \( q \) meets the affine hyperplane \( \tilde{p} + p^\perp \) at a unique point \( \frac{1}{(q,\tilde{p})} q \) which we orthogonally project to \( p^\perp \) to get \( \varphi^p(q) \). (Note that \( p^\perp \) can be identified with \( \mathbb{R}^{2n} \) simply by choosing a basis.)

The inverse of \( \varphi^p \) is the map that takes \( v \in p^\perp \) to the line through \( \tilde{p} + v \). Therefore, for \( p' \in \mathbb{C}P^n \), we see that the transition map \( \varphi^{p'} \circ (\varphi^p)^{-1} : \{ v \in p^\perp \mid v + \tilde{p} \notin p'^\perp \} \to \{ v' \in p'^\perp \mid v' + \tilde{p}' \notin p^\perp \} \) is given by

\[
v \mapsto \frac{1}{(v + \tilde{p},\tilde{p}')} (v + \tilde{p}) - \tilde{p}',
\]

and hence smooth.

Next we prove that the projection \( \pi : S^{2n+1} \to \mathbb{C}P^n \) is a smooth submersion. Let \( \tilde{p} \in S^{2n+1} \). Since the fibers of \( \pi \) are just the \( S^1 \)-orbits, the vertical space \( V_{\tilde{p}} = \mathbb{R}(i\tilde{p}) \). It follows that the horizontal space \( \mathcal{H}_{\tilde{p}} \subset T_{\tilde{p}}S^{2n+1} \) is the Euclidean orthogonal complement of \( \mathbb{R}\{\tilde{p},i\tilde{p}\} = \mathbb{C}\tilde{p} \) in \( \mathbb{C}^{2n+2} \), namely, \( p^\perp \) where \( p = \pi(\tilde{p}) \) (recall that the real part of \((\cdot,\cdot)\) is the Euclidean inner product in \( \mathbb{R}^{2n+2} \), which also induces the Riemannian metric in \( S^{2n+1} \)). It suffices to check that \( d\pi_{\tilde{p}} \) is an isomorphism from \( \mathcal{H}_{\tilde{p}} \) onto \( T_{\tilde{p}}\mathbb{C}P^n \), or, \( d(\varphi^p \circ \pi)_{\tilde{p}} \) is an isomorphism from \( p^\perp \) to itself. Let \( v \) be a unit vector in \( p^\perp \). Then \( t \mapsto \cos t \tilde{p} + \sin t v \) is a curve in \( S^{2n+1} \) with initial point \( \tilde{p} \) and initial speed \( v \), so using that \((\cos t \tilde{p} + \sin t v, \tilde{p}) = \cos t \) we have

\[
d(\varphi^p \circ \pi)_{\tilde{p}}(v) = \left. \frac{d}{dt} \right|_{t=0} (\varphi^p \circ \pi)(\cos t \tilde{p} + \sin t v) = \left. \frac{d}{dt} \right|_{t=0} \frac{1}{\cos t} (\cos t \tilde{p} + \sin t v) - \tilde{p} = v,
\]

completing the check.

Finally, we endow \( \mathbb{C}P^n \) with a Riemannian metric which makes \( \pi : S^{2n+1} \to \mathbb{C}P^n \) into a Riemannian submersion. The idea is to use the isomorphism \( d\pi_{\tilde{p}} : \mathcal{H}_{\tilde{p}} \to T_{\tilde{p}}\mathbb{C}P^n \) to transfer the
inner product from $\mathcal{H}_\tilde{p}$ to $T_p\mathbb{C}P^n$. One still has to check that choosing a different point $\tilde{p}'$ in the fiber $\pi^{-1}(p)$ yields the same result. This follows from the fact that $\tilde{p}' = z\tilde{p}$ for some $z \in S^1$, and multiplication by $z$ is a linear isometry of $\mathbb{C}^{n+1}$ which restricts to an isometry of $S^{2n+1}$ and maps $\mathcal{H}_\tilde{p}$ isometrically onto $\mathcal{H}_{\tilde{p}'}$. We refer to the next subsection for the proof of smoothness of the metric just constructed.

The quotient metric on $\mathbb{C}P^n$ constructed above is classically called the **Fubini-Study metric** on $\mathbb{C}P^n$.

**Quotient manifolds ★**

In this subsection, we generalize the discussion about $\mathbb{C}P^n$. Recall that the action of a Lie group $G$ on a smooth manifold $M$ by diffeomorphisms is called *proper* if the associated map

$$G \times M \to M \times M, \quad (g, x) \mapsto (gx, x)$$

is a proper map. An equivalent definition is to require that for any compact subsets $K, L$ of $M$, the set $\{ g \in G \mid gK \cap L \}$ is relatively compact in $G$. In the case of a discrete group, this notion coincides with that of a properly discontinuous action. We quote the following result.

1.3.3 Proposition If $\tilde{M}$ is a smooth manifold and $G$ is a Lie group acting freely and properly on $\tilde{M}$, then the quotient space $M = \tilde{M}/G$ endowed with the quotient topology admits a unique structure of smooth manifold such that the projection $\pi : \tilde{M} \to M$ is a submersion and a fiber bundle with typical fiber $G$.

In the previous proposition, if in addition we assume that $\tilde{M}$ is equipped with a Riemannian metric $\tilde{g}$ and $G$ acts on $\tilde{M}$ by isometries, then we can show that there is a unique Riemannian metric $g$ on $M$, called the *quotient metric*, so that $\pi : (\tilde{M}, \tilde{g}) \to (M, g)$ becomes a Riemannian submersion. Indeed, given a point $p \in M$ and tangent vectors $u, v \in T_pM$, we set

$$(1.3.4) \quad g_p(u, v) = \tilde{g}_{\tilde{p}}(\tilde{u}, \tilde{v}),$$

where $\tilde{p}$ is any point in the fiber $\pi^{-1}(p)$ and $\tilde{u}, \tilde{v}$ are the unique vectors in $\mathcal{H}_\tilde{p}$ satisfying $d\pi_{\tilde{p}}(\tilde{u}) = u$ and $d\pi_{\tilde{p}}(\tilde{v}) = v$. The proof that $\tilde{g}$ is well defined is similar to the proof that the quotient metric is well defined in the case of a Riemannian covering. The proof that $\tilde{g}$ is smooth is also similar, but needs an extra ingredient. Let $P_{\tilde{p}} : T_{\tilde{p}}\tilde{M} \to \mathcal{H}_\tilde{p}$ denote the orthogonal projection. It is known that $\pi : \tilde{M} \to M$ admits local sections, so let $s : U \to \tilde{M}$ be a local section defined on an open set $U$ of $M$. Now we can rewrite (1.3.4) as

$$g_q(u, v) = \tilde{g}_{s(q)}(P_{s(q)}ds_q(u), P_{s(q)}ds_q(v)),$$

where $q \in U$. Since $\mathcal{V}$ as a distribution is locally defined by smooth vector fields, it is easy to check that $P$ takes locally defined smooth vector fields on $TM$ to locally defined smooth vector fields on $TM$. It follows that $g$ is smooth. Finally, the requirement that $\pi$ be a Riemannian submersion forces $g$ to be given by formula (1.3.4), and this shows the uniqueness of $g$. □

**One-dimensional Riemannian manifolds**

Let $(M, g)$ be a Riemannian manifold and let $\gamma : [a, b] \to M$ be a piecewise $C^1$ curve. Then the **length** of $\gamma$ is defined to be

$$(1.3.5) \quad L(\gamma) = \int_a^b g_{\gamma(t)}(\gamma'(t), \gamma'(t))^{1/2} dt.$$
It is easily seen that the length of a curve does not change under re parametrization. Moreover, every regular curve (i.e. satisfying $\gamma'(t) \neq 0$ for all $t$) admits a natural parametrization given by arc-length. Namely, let

$$s(t) = \int_a^t g_{\gamma(t)}(\gamma'(\tau), \gamma'(\tau))^{1/2} \, d\tau.$$  

Then $\frac{ds}{dt} = g_{\gamma(t)}(\gamma'(t), \gamma'(t))^{1/2}(t) > 0$, so $s$ can be taken as a new parameter, and then

$$L(\gamma|_{[a, b]}) = s$$

and

\[ (\gamma^* g)_t = g_{\gamma(t)}(\gamma'(t), \gamma'(t))dt^2 = ds^2. \]

Suppose now that $(M, g)$ is a one-dimensional Riemannian manifold. Then any connected component of $M$ is diffeomorphic either to $\mathbf{R}$ or to $S^1$. In any case, a neighborhood of any point $p \in M$ can be viewed as a regular smooth curve in $M$ and, in a parametrization by arc-length, the local expression of the metric $g$ is the same, namely, given by (1.3.6). It follows that all the one-dimensional Riemannian manifolds are locally isometric among themselves.

**Lie groups ★**

The natural class of Riemannian metrics to be considered in Lie groups is the class of Riemannian metrics that possesses some kind of invariance, be it left, right or both. Let $G$ be a Lie group. A left-invariant Riemannian metric on $G$ is a Riemannian metric with respect to which the left translations of $G$ are isometries. Similarly, a right-invariant Riemannian metric is defined. A Riemannian metric on $G$ that is both left- and right-invariant is called a bi-invariant Riemannian metric.

Left-invariant Riemannian metrics (henceforth, left-invariant metrics) are easy to construct on any given Lie group $G$. In fact, given any inner product $\langle , \rangle$ in its Lie algebra $\mathfrak{g}$, which we identify with the tangent space at the identity $T_1G$, one sets $g_1 = \langle , \rangle$ and uses the left translations to pull back $g_1$ to the other tangent spaces, namely one sets

$$g_x(u, v) = g_1(Ad(L_{x^{-1}})_x(u), Ad(L_{x^{-1}})_x(v)),$$

where $x \in G$ and $u, v \in T_xG$. This defines a smooth Riemannian metric, since $g(X, Y)$ is constant (and hence smooth) for any pair $(X, Y)$ of left-invariant vector fields, and any smooth vector field on $G$ is a linear combination of left-invariant vector fields with smooth functions as coefficients. By the very construction of $g$, the $d(L_x)_1$ for $x \in G$ are linear isometries, so the composition of linear isometries $d(L_x)_y = d(L_{xy})_1 \circ d(L_y)_1^{-1}$ is also a linear isometry for $x, y \in G$. This checks that all the left-translations are isometries and hence that $g$ is left-invariant. (Equivalently, one can define $g$ by choosing a global frame of left-invariant vector fields on $G$ and declaring it to be orthonormal at every point of $G$.) It follows that the set of left-invariant metrics in $G$ is in bijection with the set of inner products on $\mathfrak{g}$. Of course, similar remarks apply to right-invariant metrics.

Bi-invariant metrics are more difficult to come up with. Starting with a fixed left-invariant metric $g$ on $G$, we want to find conditions for $g$ to be also right-invariant. Reasoning similarly as in the previous paragraph, we see that it is necessary and sufficient that the $d(R_x)_1$ for $x \in G$ be linear isometries. Further, by differentiating the obvious identity $R_x = L_x \circ \text{Inn}(x^{-1})$ at $1$, we get that

$$d(R_x)_1 = d(L_x)_1 \circ \text{Ad}(x^{-1})$$
for $x \in G$. From this identity, we get that $g$ is right-invariant if and only if the $\text{Ad}(x) : \mathfrak{g} \to \mathfrak{g}$ for $x \in G$ are linear isometries with respect to $\langle , \rangle = g_1$. In this case, $\langle , \rangle$ is called an Ad-invariant inner product on $\mathfrak{g}$.

In view of the previous discussion, applying the following proposition to the adjoint representation of a compact Lie group on its Lie algebra yields that any compact Lie group admits a bi-invariant Riemannian metric.

1.3.7 Proposition Let $\rho : G \to \text{GL}(V)$ be a representation of a Lie group on a real vector space $V$ such that the closure $\rho(G)$ is relatively compact in $\text{GL}(V)$. Then there exists an inner product $\langle , \rangle$ on $V$ with respect to which the $\rho(x)$ for $x \in G$ are orthogonal transformations.

Proof. Let $\tilde{G}$ denote the closure of $\rho(G)$ in $\text{GL}(V)$. Then $\rho$ factors through the inclusion $\tilde{\rho} : \tilde{G} \to \text{GL}(V)$ and it suffices to prove the result for $\tilde{\rho}$ instead of $\rho$. By assumption, $\tilde{G}$ is compact, so without loss of generality we may assume in the following that $G$ is compact.

Let $\langle , \rangle_0$ be any inner product on $V$ and fix a right-invariant Haar measure $dx$ on $G$. Set

$$\langle u, v \rangle = \int_G \langle \rho(x)u, \rho(x)v \rangle_0 \, dx,$$

where $u, v \in V$. It is easy to see that this defines a positive-definite bilinear symmetric form $\langle , \rangle$ on $V$. Moreover, if $y \in G$, then

$$\langle \rho(y)u, \rho(y)v \rangle = \int_G \langle \rho(x)\rho(y)u, \rho(x)\rho(y)v \rangle_0 \, dx \]
$$
$$= \int_G \langle \rho(xy)u, \rho(xy)v \rangle_0 \, dx \]
$$
$$= \langle u, v \rangle,$$

where in the last equality we have used that $dx$ is right-invariant. Note that we have used the compactness of $G$ only to guarantee that the above integrands have compact support. 

In later chapters, we will explain the special properties that bi-invariant metrics on Lie groups have.

Homogeneous spaces ★

It is apparent that for a generic Riemannian manifold $(M, g)$, the isometry group Isom$(M, g)$ is trivial. Indeed, Riemannian manifolds with large isometry groups have a good deal of symmetries. In particular, in the case in which Isom$(M, g)$ is transitive on $M$, $(M, g)$ is called a Riemannian homogeneous space or a homogeneous Riemannian manifold. Explicitly, this means that given any two points of $M$ there exists an isometry of $M$ that maps one point to the other. In this case, of course it may happen that a subgroup of Isom$(M, g)$ is already transitive on $M$.

Let $(M, g)$ be a homogeneous Riemannian manifold, and let $G$ be a subgroup of Isom$(M, g)$ acting transitively on $M$. Then the isotropy subgroup $H$ at an arbitrary fixed point $p \in M$ is compact and $M$ is diffeomorphic to the quotient space $G/H$. In this case, we also say that the Riemannian metric $g$ on $M$ is $G$-invariant.

Recall that if $G$ is a Lie group and $H$ is a closed subgroup of $G$, then there exists a unique structure of smooth manifold on the quotient $G/H$ such that the projection $G \to G/H$ is a submersion and the action of $G$ on $G/H$ by left translations is smooth. This can be seen as a particular case of Proposition 1.3.3. A manifold of the form $G/H$ is called a homogeneous space. In some cases,
one can also start with a homogeneous space \( G/H \) and construct \( G \)-invariant metrics on \( G/H \). For instance, if \( G \) is equipped with a left-invariant metric that is also right-invariant with respect to \( H \), then it follows that the quotient \( G/H \) inherits a quotient Riemannian metric such that the projection \( G \to G/H \) is a Riemannian submersion and the action of \( G \) on \( G/H \) by left translations is isometric. In this way, \( G/H \) becomes a Riemannian homogeneous space. A particular, important case of this construction is when the Riemannian metric on \( G \) that we start with is bi-invariant; in this case, \( G/H \) is called a normal homogeneous space. In general, a homogeneous space \( G/H \) for arbitrary \( G, H \) may admit several distinct \( G \)-invariant Riemannian metrics, or may admit no such metrics at all.

1.4 Exercises

1. Show that the Riemannian product of \((0, +\infty)\) and \( S^{n-1} \) is isometric to the cylinder

\[
C = \{(x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \mid x_0^2 + \cdots + x_n^2 = 1 \text{ and } x_0 > 0\}.
\]

2. The catenoid is the surface of revolution in \( \mathbb{R}^3 \) with the z-axis as axis of revolution and the catenary \( x = \cosh z \) in the \( xz \)-plane as generating curve. The helicoid is the ruled surface in \( \mathbb{R}^3 \) consisting of all the lines parallel to the \( xz \)-plane that intersect the \( z \)-axis and the helicoid \( t \mapsto (\cos t, \sin t, t) \).

a. Write natural parametrizations for the catenoid and the helicoid.

b. Consider the catenoid and the helicoid with the metrics induced from \( \mathbb{R}^3 \), and find the local expressions of these metrics with respect to the parametrizations in item (a).

c. Show that the local expressions in item (b) coincide, possibly up to a change of coordinates, and deduce that the catenoid and the helicoid are locally isometric.

d. Show that the catenoid and the helicoid cannot be isometric because of their topology.

3. Consider the real hyperbolic space \((\mathbb{R}H^n, g)\) as defined in section 1.3. Let \( \mathbb{D}^n \) be the open unit disk of \( \mathbb{R}^n \) embedded in \( \mathbb{R}^{n+1} \) as

\[
\mathbb{D}^n = \{(x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \mid x_0 = 0 \text{ and } x_1^2 + \cdots + x_n^2 < 1\}.
\]

Define a map \( f : \mathbb{R}H^n \to \mathbb{D}^n \) by setting \( f(x) \) to be the unique point of \( \mathbb{D}^n \) lying in the line joining \( x \in \mathbb{R}H^n \) and the point \((-1, 0, \ldots, 0) \in \mathbb{R}^{n+1}\). Prove that \( f \) is a diffeomorphism and, setting \( g_1 = (f^{-1})^*g \), we have that

\[
g_1|_x = \frac{4}{(1-\langle x, x \rangle)^2} \left(dx_1^2 + \cdots + dx_n^2\right),
\]

where \( x = (0, x_1, \ldots, x_n) \in \mathbb{D}^n \). Deduce that \( \mathbb{R}H^n \) is conformally flat.

\((\mathbb{D}^n, g_1)\) is called the Poincaré disk model of \( \mathbb{R}H^n \).

4. Consider the open unit disk \( \mathbb{D}^n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_1^2 + \cdots + x_n^2 < 1\} \) equipped with the metric \( g_1 \) as in Exercise 3. Prove that the inversion of \( \mathbb{R}^n \) on the sphere of center \((-1, 0, \ldots, 0)\) and radius \( \sqrt{2} \) defines a diffeomorphism \( f_1 \) from \( \mathbb{D}^n \) onto the upper half-space

\[
\mathbb{R}^n_+ = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_1 > 0\},
\]

and that the metric \( g_2 = (f_1^{-1})^*g_1 \) is given by

\[
g_2|_x = \frac{1}{x_1^2} \left(dx_1^2 + \cdots + dx_n^2\right),
\]

12
where \( x = (x_1, \ldots, x_n) \in \mathbb{R}^n_+ \).

\((\mathbb{R}^n_+, g_2)\) is called the Poincaré upper half-space model of \( \mathbb{R}H^n \).

5 Consider the Poincaré upper half-plane model \( \mathbb{R}_2^+ = \{(x, y) \in \mathbb{R}^2 \mid y > 0\} \) with the metric \( g_2 = \frac{1}{y} (dx^2 + dy^2) \) (case \( n = 2 \) in Exercise 4). Check that the following transformations of \( \mathbb{R}^2_+ \) into itself are isometries:

a. \( \tau_a(x, y) = (x + a, y) \) for \( a \in \mathbb{R} \);

b. \( h_r(x, y) = (rx, ry) \) for \( r > 0 \);

c. \( R(x, y) = \left(\frac{x}{x^2 + y^2}, \frac{y}{x^2 + y^2}\right) \).

Deduce from (a) and (b) that \( \mathbb{R}^2_+ \) is homogeneous.

6 Use stereographic projection to prove that \( S^n \) is conformally flat.

7 Consider the parametrized curve

\[
\begin{align*}
  x &= t - \tanh t \\
  y &= \frac{1}{\cosh t}
\end{align*}
\]

The surface of revolution in \( \mathbb{R}^3 \) constructed by revolving it around the \( x \)-axis is called the pseudo-sphere. Note that the pseudo-sphere is singular along the circle obtained by revolving the point \((0, 1)\).

a. Prove that the pseudo-sphere with the singular circle taken away is locally isometric to the upper half plane model of \( \mathbb{R}H^2 \).

b. Show that the Gaussian curvature of the pseudo-sphere is \(-1\).

8 Let \( \Gamma \) be the lattice in \( \mathbb{R}^n \) defined by the basis \( \{v_1, \ldots, v_n\} \), and denote by \( g_\Gamma \) the Riemannian metric that it defines on \( T^n \). Show that in some product chart of \( T^n = S^1 \times \cdots \times S^1 \) the local expression

\[ g_\Gamma = \sum_{i,j} \langle v_i, v_j \rangle \, dx_i \otimes dx_j \]

holds, where \( \langle , \rangle \) denotes the standard scalar product in \( \mathbb{R}^n \).

9 Let \( \Gamma \) and \( \Gamma' \) be two lattices in \( \mathbb{R}^n \), and denote by \( g_\Gamma \), \( g_{\Gamma'} \) the Riemannian metrics that they define on \( T^n \), respectively. Prove that \((T^n, g_\Gamma)\) is isometric to \((T^n, g_{\Gamma'})\) if and only if there exists an isometry \( f : \mathbb{R}^n \to \mathbb{R}^n \) such that \( f(\Gamma) = \Gamma' \). (Hint: You may use the result of exercise 2 of chapter 3.)

10 Let \( \Gamma \) be the lattice of \( \mathbb{R}^2 \) spanned by an orthogonal basis \( \{v_1, v_2\} \) and consider the associated rectangular flat torus \( T^2 \).

a. Prove that the map \( \gamma \) of \( \mathbb{R}^2 \) defined by \( \gamma(x_1v_1 + x_2v_2) = (x_1 + \frac{1}{2})v_1 - x_2v_2 \) induces an isometry of \( T^2 \) of order two.

b. Prove that \( T^2 \) double covers a Klein bottle \( K^2 \).

11 Prove that \( \mathbb{R}^n \setminus \{0\} \) is isometric to the warped product \(((0, +\infty) \times S^{n-1}, dr^2 + r^2 g)\), where \( r \) denotes the coordinate on \((0, +\infty)\) and \( g \) denotes the standard Riemannian metric on \( S^{n-1} \).
12 Let $G$ be a Lie group equal to one of $O(n)$, $U(n)$ of $SU(n)$, and denote its Lie algebra by $\mathfrak{g}$. Prove that for any $c > 0$

$$\langle X, Y \rangle = -c \trace(XY),$$

where $X, Y \in \mathfrak{g}$, defines an Ad-invariant inner product on $\mathfrak{g}$.

13 Consider the special unitary group $SU(2)$ equipped with a bi-invariant metric induced from an Ad-invariant inner product on $\mathfrak{su}(2)$ as in the previous exercise with $c = \frac{1}{2}$. Show that the map

$$\begin{pmatrix} \alpha & -\bar{\beta} \\ \beta & \bar{\alpha} \end{pmatrix} \mapsto \begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

where $\alpha, \beta \in \mathbb{C}$ and $|\alpha|^2 + |\beta|^2 = 1$, defines an isometry from $SU(2)$ to $S^3$. Here $\mathbb{C}^2$ is identified with $\mathbb{R}^4$ and $S^3$ is viewed as the unit sphere in $\mathbb{R}^4$.

14 Show that $\mathbb{R}P^1$ equipped with the quotient metric from $S^1(1)$ is isometric to $S^1(\frac{1}{2})$. Show that $\mathbb{C}P^1$ equipped with the Fubini-Study metric is isometric to $S^2(\frac{1}{2})$.

1.5 Additional notes

§1 Riemannian manifolds were defined as abstract smooth manifolds equipped with Riemannian metrics. One class of examples of Riemannian manifolds is of course furnished by the Riemannian submanifolds of Euclidean space. On the other hand, a very deep theorem of Nash [Nas56] states that every abstract Riemannian manifold admits an isometric embedding into Euclidean space, so that it can be viewed as an embedded Riemannian submanifold of Euclidean space. In view of this, one might be tempted to ask why bother to consider abstract Riemannian manifolds in the first place. The reason is that Nash’s theorem is an existence result: for a given Riemannian manifold, it does not supply an explicit embedding of it into Euclidean space. Even if an isometric embedding is known, there may be more than one or there may be no canonical embedding. Also, an explicit embedding may be too complicated to describe. Finally, a particular embedding is sometimes distracting because it highlights some specific features of the manifold at the expense of some other features, which may be undesirable.

§2 From the point of view of foundations of the theory of smooth manifolds, the following assertions are equivalent for a smooth manifold $M$ whose underlying topological space is assumed to be Hausdorff but not necessarily second-countable:

a. The topology of $M$ is paracompact.

b. $M$ admits smooth partitions of unity.

c. $M$ admits Riemannian metrics.

In fact, as is standard in the theory of smooth manifolds, second-countability of the topology of $M$ (together with the Hausdorff property) implies its paracompactness and this is used to prove the existence of smooth partitions of unity [War83, chapter 1]. Next, Riemannian metrics are constructed on $M$ by using partitions of unity as we did in Proposition 1.2.3. Finally, the underlying topology of a Riemannian manifold is metrizable according to Proposition 3.2.3, and every metric space is paracompact.

§3 The pseudo-sphere constructed in Exercise 7 was introduced by Beltrami [Bel68] in 1868 as a local model for the Lobachevskyan geometry. This means that the geodesic lines and their segments on the pseudo-sphere play the role of straight lines and their segments on the Lobachevsky plane. In 1900, Hilbert posed the question of whether there exists a surface in three-dimensional Euclidean space whose intrinsic geometry coincides completely with the geometry of the Lobachevsky plane.
Using a simple reasoning, it follows that if such a surface does exist, it must have constant negative curvature and be complete (see chapter 3 for the notion of completeness).

As early as 1901, Hilbert solved this problem [Hil01] (see also [Hop89, chapter IX]), and in the negative sense, so that no complete surface of constant negative curvature exists in three-dimensional Euclidean space. This theorem has attracted the attention of geometers over a number of decades, and continues to do so today. The reason for this is that a number of interesting questions are related to it and to its proof. For instance, the occurrence of a singular circle on the pseudo-sphere is not coincidental, but is in line with Hilbert’s theorem.
