Important: Before reading GB_BOOKS, please read or at least skim the programs for GB_GRAPH and GB_IO.

1. Introduction. This GraphBase module contains the book subroutine, which creates a family of undirected graphs that are based on classic works of literature. It also contains the bi_book subroutine, which creates a related family of bipartite graphs. An example of the use of book can be found in the demonstration program BOOK_COMPONENTS.

2. The subroutine call book((title), n, x, first_chapter, last_chapter, in_weight, out_weight, seed) constructs a graph based on the information in (title).dat, where (title) is either "anna" (for Anna Karenina), "david" (for David Copperfield), "jean" (for Les Misérables), "huck" (for Huckleberry Finn), or "homer" (for The Iliad). Each vertex of the graph corresponds to one of the characters in the selected book. Edges between vertices correspond to encounters between those characters. The length of each edge is 1.

Subsets of the book can be selected by specifying that the edge data should be restricted to chapters between first_chapter and last_chapter, inclusive. If first_chapter = 0, the result is the same as if first_chapter = 1. If last_chapter = 0 or if last_chapter exceeds the total number of chapters in the book, the result is the same as if last_chapter were the number of the book’s final chapter.

The constructed graph will have min(n, N) – x vertices, where N is the total number of characters in the selected book. However, if n is zero, n is automatically made equal to the maximum possible value, N. If n is less than N, the n – x characters will be selected by assigning a weight to each character and choosing the n with largest weight, then excluding the largest x of these, using random numbers to break ties in case of equal weights. Weights are computed by the formula

\[ \text{in_weight} \cdot \text{chapters_in} + \text{out_weight} \cdot \text{chapters_out}, \]

where \text{chapters_in} is the number of chapters between first_chapter and last_chapter in which a particular character appears, and \text{chapters_out} is the number of other chapters in which that character appears. Both \text{in_weight} and \text{out_weight} must be at most 1,000,000 in absolute value.

Vertices of the graph will appear in order of decreasing weight. The seed parameter defines the pseudo-random numbers used wherever a “random” choice between equal-weight vertices needs to be made. As usual with GraphBase routines, different choices of seed will in general produce different selections, but in a system-independent manner; identical results will be obtained on all computers when identical parameters have been specified. Any seed value between 0 and \(2^{31} - 1\) is permissible.
3. Examples: The call book("anna", 0, 0, 0, 0, 0, 0) will construct a graph on 138 vertices that represent all 138 characters of Tolstoy's Anna Karenina, as recorded in anna.dat. Two vertices will be adjacent if the corresponding characters encounter each other anywhere in the book. The call book("anna", 50, 0, 0, 0, 1, 1, 0) is similar, but it is restricted to the 50 characters that occur most frequently, i.e., in the most chapters. The call book("anna", 50, 0, 10, 120, 1, 1, 0) has the same vertices, but it has edges only for encounters that take place between chapter 10 and chapter 120, inclusive. The call book("anna", 50, 0, 10, 120, 1, 0, 0) is similar, but its vertices are the 50 characters that occur most often in chapters 10 through 120, without regard to how often they occur in the rest of the book. The call book("anna", 50, 0, 10, 120, 0, 0, 0) is also similar, but it chooses 50 characters completely at random (possibly from those that don’t occur in the selected chapters at all).

Parameter x, which causes the x vertices of highest weight to be excluded, is usually either 0 or 1. It is provided primarily so that users can set x = 1 with respect to David Copperfield and Huckleberry Finn; those novels are narrated by their principal character, so they have edges between the principal character and almost everybody else. (Characters cannot get into the action of a first-person account unless they encounter the narrator or unless the narrator is quoting some other person’s story.) The corresponding graphs tend to have more interesting connectivity properties if we leave the narrator out by setting x = 1. For example, there are 87 characters in David Copperfield; the call book("david", 0, 1, 0, 0, 1, 1, 0) produces a graph with 86 vertices, one for every character except David Copperfield himself.

4. The subroutine call bi_book (title, n, x, first_chapter, last_chapter, in_weight, out_weight, seed) produces a bipartite graph in which the vertices of the first part are exactly the same as the vertices of the graph returned by book, while the vertices of the second part are the selected chapters. For example, bi_book("anna", 50, 0, 10, 120, 1, 1, 0) creates a bipartite graph with 50 + 111 vertices. There is an edge between each character and the chapters in which that character appears.

5. Chapter numbering needs further explanation. Anna Karenina has 239 chapters, which are numbered 1.1 through 8.19 in the work itself but renumbered 1 through 239 as far as the book routine is concerned. Thus, setting first_chapter = 10 and last_chapter = 120 turns out to be equivalent to selecting chapters 1.10 through 4.19 (more precisely, chapter 10 of book 1 through chapter 19 of book 4). Les Misérables has an even more involved scheme: its 356 chapters range from 1.1.1 (part 1, book 1, chapter 1) to 5.9.6 (part 5, book 9, chapter 6). After book or bi_book has created a graph, the external integer variable chapters will contain the total number of chapters, and chap_name will be an array of strings containing the structured chapter numbers. For example, after book("jean", ...), we will have chapters = 356, chap_name[1] = "1.1.1", ..., chap_name[356] = "5.9.6"; chap_name[0] will be "".

#define MAX_CHAPS 360 /* no book will have this many chapters */

(External variables 5) ≡

long chapters; /* the total number of chapters in the selected book */
char *chap_name[MAX_CHAPS] = {""}; /* string names of those chapters */

This code is used in section 8.

6. As usual, we put declarations of the external variables into the header file for users to include.

(\texttt{gb\_books.h \ 1}) ≡

extern long chapters; /* the total number of chapters in the selected book */
extern char *chap_name[]; /* string names of those chapters */

7. If the book or bi_book routine encounters a problem, it returns Λ (NULL), after putting a code number into the external variable panic_code. This code number identifies the type of failure. Otherwise book returns a pointer to the newly created graph, which will be represented with the data structures explained in \texttt{gb\_graphs}. (The external variable panic_code is itself defined in \texttt{gb\_graphs}.)

#define panic (c) { panic\_code = c; gb\_trouble\_code = 0; return Λ; }

format node long /* the node type is defined below */
§8  GB_BOOKS

8. The C file gb_books.c has the overall shape shown here. It makes use of an internal subroutine called
bgraph, which combines the work of book and bi_book.

```c
#include "gb_io.h" /* we will use the GB_IO routines for input */
#include "gb_flip.h"    /* we will use the GB_FLIP routines for random numbers */
#include "gb_graph.h"  /* we will use the GB_GRAPH data structures */
#include "gb_sort.h"   /* and the gb MSNBC routine */

(Preprocessor definitions)

( Type declarations 13)
( Private variables 11)
( External variables 5)

static Graph *bgraph(bipartite, title, n, x, first_chapter, last_chapter, in_weight, out_weight, seed)
    long bipartite;    /* should we make the graph bipartite? */
    char *title;      /* identification of the selected book */
    unsigned long n; /* number of vertices desired before exclusion */
    unsigned long x; /* number of vertices to exclude */
    unsigned long first_chapter, last_chapter;    /* interval of chapters leading to edges */
    long in_weight;    /* weight coefficient pertaining to chapters in that interval */
    long out_weight;   /* weight coefficient pertaining to chapters not in that interval */
    long seed;         /* random number seed */
{
    ( Local variables 9)

    gb_init_rand(seed);
    ( Check that the parameters are valid 10);
    ( Skip the data file, recording the characters and computing their statistics 15);
    ( Choose the vertices and put them into an empty graph 27);
    ( Read the data file more carefully and fill the graph as instructed 29);
    if (gb_trouble_code) {
        gb_recycle(new_graph);
        panic(allocfault);    /* (expletive deleted) we ran out of memory somewhere back there */
    }
    return new_graph;

    char *title;
    unsigned long n, x, first_chapter, last_chapter;
    long in_weight, out_weight, seed;
{ return bgraph(0L, title, n, x, first_chapter, last_chapter, in_weight, out_weight, seed); }

Graph *bi_book(title, n, x, first_chapter, last_chapter, in_weight, out_weight, seed)
    char *title;
    unsigned long n, x, first_chapter, last_chapter;
    long in_weight, out_weight, seed;
{ return bgraph(1L, title, n, x, first_chapter, last_chapter, in_weight, out_weight, seed); }

9. (Local variables 9) ≡

Graph *new_graph;    /* the graph constructed by book or bi_book */
register long j, k;    /* all-purpose indices */
register characters;   /* the total number of characters in the selected book */
register node *p;    /* information about the current character */

See also section 21.

This code is used in section 8.
10. #define MAX_CHARS 600 /* there won't be more characters than this */
(Check that the parameters are valid 10)  
  if (n == 0) n = MAX_CHARS;  
  if (first chapter == 0) first chapter = 1;  
  if (last chapter == 0) last chapter = MAX_CHAPS;  
  if (in weight > 1000000 ∨ in weight < -1000000 ∨ out weight > 1000000 ∨ out weight < -1000000)  
    panic (bad_specs); /* the magnitude of at least one weight is too big */
    sprintf (filename, "%.6s.dat", title);  
  if (gb open (filename) != 0) panic (early data fault); /* couldn't open the file; w errors tells why */
This code is used in section 8.

11. (Private variables 11)  
    static char filename [] = "xxxxxx.dat";
See also sections 14 and 24.
This code is used in section 8.
12. **Vertices.** Each character in a book has been given a two-letter code name for internal use. The
code names are explained at the beginning of each data file by a number of lines that look like this:

```
XX (name), (description)
```

For example, here's one of the lines near the beginning of "anna.dat":

```
AL Alexey Alexandrovitch Karenin, minister of state
```

The (name) does not contain a comma; the (description) might.

A blank line follows the cast of characters.

Internally, we will think of the two-letter code as a radix-36 integer. Thus AA will be the number 
10 × 36 + 10, and ZZ will be 35 × 36 + 35. The `gb_number` routine in `GB_IO` is set up to input radix-36 integers just as it
does hexadecimal ones. In The Iliad, many of the minor characters have numeric digits in their code names because the total number of characters is too large to permit mnemonic codes for everybody.

```
#define MAX_CODE 1296  /* 36 × 36, the number of two-digit codes in radix 36 */
```

13. In order to choose the vertices, we want to represent each character as a node whose key corresponds
to its weight; then the `gb_linksort` routine of `GB_SORT` will provide the desired rank-ordering. We will find
it convenient to use these nodes for all the data processing that `bygraph` has to do.

```
typedef struct node_struct {
    long key;       /* the nonnegative sort key (weight plus 2^30) */
    struct node_struct *link;  /* pointer to next record */
    long code;      /* code number of this character */
    long in;        /* number of occurrences in selected chapters */
    long out;       /* number of occurrences in unselected chapters */
    long chap;      /* seen most recently in this chapter */
    Vertex *vert;   /* vertex corresponding to this character */
} node;
```

This code is used in section 8.

14. Not only do nodes point to codes, we also want codes to point to nodes.

```
(Private variables 11) +≡
static node node_block[MAX_CHARS]; /* array of nodes for working storage */
static node *xnode[MAX_CODE];       /* the node, if any, having a given code */
```

15. We will read the data file twice, once quickly (to collect statistics) and once more thoroughly (to record
detailed information). Here is the quick version.

```
(Skim the data file, recording the characters and computing their statistics 15) ≡
(Read the character codes at the beginning of the data file, and prepare a node for each one 16);
(Skim the chapter information, counting the number of chapters in which each character appears 19);
if (gb_close() ≠ 0) panic (late data fault);  /* checksum or other failure in data file; see io_errors */
```

This code is used in section 8.
16. \(\text{Read the character codes at the beginning of the data file, and prepare a node for each one} 16\) \(\equiv\)

18. \( \text{gb_books.h} \) \n
#define desc z.  S  /* utility field definitions for the header file */
#define in_count y.  I
#define out_count x.  I
#define short_code u.  I
19. Edges. The second part of the data file has a line for each chapter, containing "cliques of encounters." For example, the line

3.22:AA, BB, CC, DD; CC, DD, EE; AA, FF

means that, in chapter 22 of book 3, there were encounters between the pairs

(The encounter CC–DD is specified twice, once in the clique AA, BB, CC, DD and once in CC, DD, EE; this does not imply anything about the actual number of encounters between CC and DD in the chapter.)

A clique might involve one character only, when that character is featured in sort of a soliloquy.

A chapter might contain no references to characters at all. In such a case the ':' following the chapter number is omitted.

There might be more encounters than will fit on a single line. In such cases, continuation lines begin with ' &'. This convention turns out to be needed only in homer.dat; chapters in The Iliad are substantially more complex than the chapters in other GraphBase books.

On our first pass over the data, we simply want to compute statistics about who appears in what chapters, so we ignore the distinction between commas and semicolons.

(Skim the chapter information, counting the number of chapters in which each character appears 19) \( \equiv \)

```c
for (k = 1; k < MAX_CHAPS && gb_eof(); k++) {
    gb_string(strbuf, ':'); /* read past the chapter number */
    if (strbuf[0] == '?' && k--) /* continuation of previous chapter */
        while (gb_char() != 'n') { register long c = gb_number(36);
            if (c >= MAX_CODE) panic(syntax_error + 4); /* missing punctuation between characters */
                p = node[c];
                if (p) panic(syntax_error + 5); /* unknown character */
                if (p->chap != k) {
                    p->chap = k;
                    if (k >= first_chapter && k <= last_chapter) p->in++;
                } else p->out++;
        }
    gb_newline();
}
```

if (k == MAX_CHAPS) panic(syntax_error + 6); /* too many chapters */

This code is used in section 15.
20. Our second pass over the data is very similar to the first, if we are simply computing a bipartite graph. In that case we add an edge to the graph between each selected chapter and each selected character in that chapter. Local variable `chap_base` will point to a vertex such that `chap_base + k` is the vertex corresponding to chapter `k`.

The `in_count` of a chapter vertex is the degree of that vertex, i.e., the number of selected characters that appear in the corresponding chapter. The `out_count` is the number of characters that appear in the chapter but were omitted from the graph. Thus the `in_count` and `out_count` for chapters are analogous to the `in_count` and `out_count` for characters.

(Read the chapter information a second time and create the appropriate bipartite edges) 20

\[
\begin{align*}
\text{for } (p = \text{node\_block}; p < \text{node\_block} + \text{characters}; p++) & \ p-\text{chap} = 0; \\
\text{for } (k = 1; \neg \text{gb\_eof}(); k++) & \ {
\text{gb\_string}(\text{str\_buf}, '\;'); /* read the chapter number */ \\
\text{if } (\text{str\_buf}[0] \equiv ' & ') & \ k--; \\
\text{else } \text{chap\_name}[k] = \text{gb\_save\_string}(\text{str\_buf}); \\
\text{if } (k \geq \text{first\_chapter} \land k \leq \text{last\_chapter}) & \ { \text{register} \ Vertex \ u = \text{chap\_base} + k; \\
\text{if } (\text{str\_buf}[0] \neq ' & ') & \ {{
\begin{align*}
& u-\text{name} = \text{chap\_name}[k]; \\
& u-\text{desc} = \text{null\_string}; \\
& u-\text{in\_count} = u-\text{out\_count} = 0;
\end{align*}
}} \\
\text{while } (\text{gb\_char}() \neq ' \backslash n') & \ { \text{register} \ long \ c = \text{gb\_number}(36); \\
& p = x\text{node}[c]; \\
& \text{if } (p-\text{chap} \neq k) & \ { \text{register} \ Vertex \ v = p-\text{vert}; \\
&& p-\text{chap} = k; \\
&& \text{if } (v) & \ { \text{gb\_new\_edge}(v, u, 1); \\
& & u-\text{in\_count}++; \\
&& \text{else } u-\text{out\_count}++; \\
& } \\
& } \\
& \text{gb\_newline}(); \\
\end{align*}
}
\]

21. (Local variables 9) +\equiv

\[
\text{Vertex} * \text{chap\_base}; /* the bipartite vertex for chapter } k \text{ is chap\_base } + k */
\]
22. The second pass has to work a little harder when we are recording encounters from cliques, but the logic isn’t difficult really. We insert a reference to the first chapter that generated each edge, in utility field chap_no of the corresponding Arc record.

```c
#define chap_no a.I /* utility field a holds a chapter number */

(Read the chapter information a second time and create the appropriate edges for encounters 22) 

for (k = 1; gb_eof(); k++) { char *s;
    s = gb_string(str_buf[1]); /* read the chapter number */
    if (str_buf[0] == '\n') k--;
    else { if (*s < 2) s = s - 2; s = s + 1; }
    chap_name[k] = gb_save_string(str_buf);
}

if (k > first_chapter && k < last_chapter) { register long c = gb_char();
    while (c != '\n') { register Vertex **pp = clique_table;
        register Vertex **qq, **rr; /* pointers within the clique table */
        do { c = gb_number(36); /* set c to code for next character of clique */
            if (xnode[c] == vert) /* is that character a selected vertex? */
                *pp++ = xnode[c] - vert; /* if so, that vertex joins the current clique */
                c = gb_char();
        } while (c != '\n'); /* repeat until end of the clique */
        for (qq = clique_table; qq + 1 < pp; qq++)
            for (rr = qq + 1; rr < pp; rr++)
                (Make the vertices *qq and *rr adjacent, if they aren’t already 25);
    }
    gb_newline();
}
```

This code is used in section 29.

23. (gb_books.h 1) +=

```c
#define chap_no a.I /* utility field definition in the header file */
```

24. (Private variables 11) +=

```c
static Vertex *clique_table[30]; /* pointers to vertices in the current clique */
```

25. (Make the vertices *qq and *rr adjacent, if they aren’t already 25) +=

```c
{ register Vertex *u = *qq, *v = *rr;
    register Arc *a;
    for (a = w-arcs; a; a = a->next)
        if (a-tip == v) goto found;
    gb_new_edge(u, v, 1); /* not found, so they weren’t already adjacent */
    if (u < v) a = w-arcs;
    else a = v-arcs; /* the new edge consists of arcs a and a + 1 */
    a->chap_no = ((a + 1)->chap_no = k);
    found:;
}
```

This code is used in section 22.
26. Administration. The program is now complete except for a few missing organizational details. I will add these after lunch.

27. OK, I'm back; what needs to be done? The main thing is to create the graph itself.

\[
\begin{align*}
&\text{(Choose the vertices and put them into an empty graph 27)} \\
&\quad \text{if } (n > \text{characters}) \ n = \text{characters}; \\
&\quad \text{if } (x > n) \ x = n; \\
&\quad \text{if } (\text{last chapter} > \text{chapters}) \ \text{last chapter} = \text{chapters}; \\
&\quad \text{if } (\text{first chapter} > \text{last chapter}) \ \text{first chapter} = \text{last chapter} + 1; \\
&\quad \text{new graph} = \text{gb_new_graph}(n - x + (\text{bipartite? last chapter} - \text{first chapter} + 1 : 0)); \\
&\quad \text{if } (\text{new graph} \equiv \Lambda) \ \text{panic (no room)}; \\
&\text{strcpy(new graph-utility_types, "ZZZZZZZZZZZ");} \\
&\text{*/ declare the types of utility fields */} \\
&\text{sprintf(new graph-id, "\%s\x", \%lu, \%lu, \%lu, \%lu, \%lu, \%lu, \%lu, \%lu")}; \\
&\text{bipartite? "bi_": ", title,} \\
&\text{n, x, first chapter, last chapter, in_weight, out_weight, seed);} \\
&\text{(bipartite)} \ \\
&\quad \text{mark_bipartite(new graph, n - x);} \\
&\quad \text{chap base = new graph-vertices + (new graph-n+1 - first chapter);} \\
&\end{align*}
\]

\[
\text{(Compute the weights and assign vertices to chosen nodes 28)};
\]

This code is used in section 8.

28. \[
\begin{align*}
&\text{(Compute the weights and assign vertices to chosen nodes 28)} \ \
&\text{for } (p = \text{node block}; p < \text{node block} + \text{characters}; p++) \\
&\quad p \text{ key} = \text{in_weight} * (p - \text{in}) + \text{out_weight} * (p - \text{out}) + \#40000000; \\
&\quad \text{gb_LinkSort(node block + characters - 1)}; \\
&\quad k = n; \quad /\!* \text{we will look at this many nodes */} \\
&\quad \text{register Vertex } *v = \text{new graph-vertices}; \quad /\!* \text{the next vertex to define */} \\
&\quad \text{for } (j = 127; j \geq 0; j--) \\
&\quad \quad \text{for } (p = (\text{node } *) \ \text{gb_sorted}[j]; p; p = p \text{ - link}) \ \\

(Check that the parameters are valid 10)  Used in section 8.
(Choose the vertices and put them into an empty graph 27)  Used in section 8.
(Compute the weights and assign vertices to chosen nodes 28)  Used in section 27.
(External variables 5)  Used in section 8.
(Local variables 9, 21)  Used in section 8.
(Make the vertices *qq and *rr adjacent, if they aren’t already 25)  Used in section 22.
(Private variables 11, 14, 24)  Used in section 8.
(Read the chapter information a second time and create the appropriate bipartite edges 20)  Used in section 29.
(Read the chapter information a second time and create the appropriate edges for encounters 22)  Used in section 29.
(Read the character codes at the beginning of the data file, and prepare a node for each one 16)  Used in section 15.
(Read the data about characters again, noting vertex names and the associated descriptions 17)  Used in section 29.
(Read the data file more carefully and fill the graph as instructed 29)  Used in section 8.
(Skim the chapter information, counting the number of chapters in which each character appears 19)  Used in section 15.
(Skim the data file, recording the characters and computing their statistics 15)  Used in section 8.
(Type declarations 13)  Used in section 8.

This file may be freely copied and distributed, provided that no changes whatsoever are made. All users are asked to help keep the Stanford GraphBase files consistent and "uncorrupted," identical everywhere in the world. Changes are permissible only if the modified file is given a new name, different from the names of existing files in the Stanford GraphBase, and only if the modified file is clearly identified as not being part of that GraphBase. (The OEB system has a "change file" facility by which users can easily make minor alterations without modifying the master source files in any way. Everybody is supposed to use change files instead of changing the files.) The author has tried his best to produce correct and useful programs, in order to help promote computer science research, but no warranty of any kind should be assumed.

Preliminary work on the Stanford GraphBase project was supported in part by National Science Foundation grant CCR-86-10181.
